Problem 1

 \mathbf{a}

From the joint pmf, we have

$$c + 0.1 + 0.1 + 0.2 + 0.1 + 0.2 + 0.1 + 0.1 = 1$$

 $c = 0.1$

b

From definition of joint cdf, $F_{XY}(2,1)$ will be

$$F_{XY}(2,1) = \sum_{x \le 2, y \le 1} p_{XY}(j,k)$$
$$= 0.1 + 0.1 + 0.2 + 0.1$$
$$= 0.5$$

 \mathbf{c}

From the table of pmf, by summing up the $p_{XY}(j,k)$ in each row / column, we have

j	1	2	3	4	otherwise
$P_X(j)$	0.3	0.3	0.2	0.2	0

k	0	1	2	otherwise
$P_Y(k)$	0.3	0.5	0.2	0

 \mathbf{d}

No, a counterexample would be (4,1), where $P_{XY}(4,1) \neq P_X(4) \times P_Y(1)$

 \mathbf{e}

Yes, by calculating the covarience of X, Y, we have

$$Cov(X,Y) = E(XY) - E(X)E(Y)$$

= 1.8 - 2.07
= -0.27 \neq 0,

which means X, Y are correlated.

 \mathbf{f}

First, calculate standard variation of X, Y

$$\sigma_X = (E(X^2) - (E(X))^2)^{1/2}$$

$$= (6.2 - 2.3^2)^{1/2}$$

$$= foo$$

$$\sigma_Y = (E(X^2) - (E(X))^2)^{1/2}$$

$$= (1.3 - 0.9^2)^{1/2}$$

$$= bar$$

$$r = Cov(X, Y) / \sigma_X \sigma_Y$$

$$= foobar$$

g

From the marginal pmf of Y, we have P(Y < 1) = 0.3, then the conditional pmf of X can be calculated using $P_{X|Y<1}(j) = P(j, Y < 1)/P(Y < 1)$, We have

j	1	2	3	4	otherwise
$P_{X Y<1}(j)$	1/3	1/3	0	1/3	0

h

From the conditional pmf in g, the conditional expected value of X is

$$E(X|Y < 1) = \sum_{j} j * P_{X|Y < 1}(j)$$

= 7/3

Problem 2

 \mathbf{a}

From the joint pmf of X, Z, we have

$$P_X(x) = \sum_{z=x}^{+\infty} \frac{3^z}{x!(z-x)!} 0.4^x 0.6^{z-x} e^{-3}$$

$$= \frac{1.2^x}{x!} e^{-3} \sum_{t=0}^{+\infty} \frac{1.8^t}{t!} \quad (let \ t = z - x)$$

$$= \frac{1.2^x}{x!} e^{-1.2}$$

It belongs to Poisson distribution with mean 1.2

b

From the joint pmf of X, Z, we have

$$P_Z(z) = \sum_{x=0}^{z} \frac{3^z}{x!(z-x)!} 0.4^x 0.6^{z-x} e^{-3}$$

$$= \frac{3^z}{z!} e^{-3} \sum_{x=0}^{z} \frac{z!}{x!(z-x)!} 0.4^x 0.6^{z-x}$$

$$= \frac{3^z}{z!} e^{-3}$$

It belongs to Poisson distribution with mean 3

 \mathbf{c}

For Z = X + Y, we have

$$P_Y(y) = \sum_{x=0}^{+\infty} \frac{3^{x+y}}{x!y!} 0.4^x 0.6^y e^{-3}$$

$$= \frac{1.8^y}{y!} e^{-3} \sum_{x=0}^{+\infty} \frac{3^x}{x!} 0.4^x$$

$$= \frac{1.8^y}{y!} e^{-1.8}$$
(1)

It belongs to Poisson distribution with mean 1.8

 \mathbf{d}

No, a counterexample will be (x, z) = (1, 0), for neither of $P_X(1)$, $P_Z(0)$ equals zero, but by definition $P_{X,Z}(1,0) = 0$

 \mathbf{e}

Yes, for

$$P_{X,Y}(x,y) = P_{X,Z}(x, x + y) \quad (by \ definition)$$

$$= \frac{3^{x+y}}{x!((x+y)-x)!} 0.4^x 0.6^{(x+y)-x} e^{-3}$$

$$= \frac{3^{x+y}}{x!y!} 0.4^x 0.6^y e^{-3}$$

$$= \frac{1.2^x}{x!} e^{-1.2} \times \frac{1.8^y}{y!} e^{-1.8}$$

$$= P_X(x) \times P_Y(y)$$

 \mathbf{f}

From the pmf of X, Z and marginal pmf of Z, we have

$$P_{X|Z}(x) = \left(\frac{3^z}{x!(z-x)!} 0.4^x 0.6^{z-x} e^{-3}\right) / \left(\frac{3^z}{z!} e^{-3}\right)$$
$$= \frac{z!}{x!(z-x)!} 0.4^x 0.6^{z-x},$$

which belongs to binomial distribution with paremeter (n, p) = (z, 0.4).

 \mathbf{g}

From the result in (f), the conditional expectation of X is E[X|Z] = 0.4Z.
